

ABSTRACT OF THE DISCLOSURE

An improved dispenser for thin, flexible hand coverings includes a unique mechanism to retain the opposing edges of the flexible film as it is advanced and applied to the hand, thereby promoting a controlled stretching, adherence and release. In the preferred embodiment, the entrapment of the film edges is carried out using interlocking 5 chains that advance through guide channels. Another improvement is that the housing of the dispenser in this case is raised as the user pulls down the film to be adhered, and it is the weight of the dispenser that causes the unit to reset for the next use, thereby eliminating the need for springs, at least for this purpose.
